## (54) PRODUCTION OF PAPER OF PAPERBOARD

### (57)Abstract:

PROBLEM TO BE SOLVED: To obtain a paper or a paperboard, good in fixing property to a pulp and excellent in paper force strength by making the paper after adding a (meth)acrylamide-based water dispersible high molecular weight material containing a specific phosphoric acid group to the pulp slurry containing a prescribed amount of calcium ion.

SOLUTION: This method for producing a paper or a paperboard comprises making the paper after adding preferably 0.1-1wt.% (based on the solid portion of a pulp) (meth)acrylamide-based water dispersible high molecular weight material containing a phosphoric acid group of formula I (X is H, a 1-4C hydrocarbon or an alkali metal) as a paper force strength reinforcing agent

to the pulp slurry containing 50-5000ppm calcium ion. Further, the (meth)acrylamide-based water dispersible high molecular weight material containing the phosphoric acid group is preferably a water dispersible high molecular weight material consisting of (meth)acrylamide and a monomer containing phosphoric acid group of formula II (X is H, a 1-6C hydrocarbon or an alkali metal) as main constituting components. Also, pH of the paper making system can be applicable from an acid region to an alkaline region.

DETAILED DESCRIPTION

---

[Detailed Description of the Invention]

[0001]

[Field of the Invention] This invention relates to the manufacture approach of paper or the paper board. In detail, calcium ion is related with the approach of manufacturing the paper or the paper board which has the outstanding paper durability reinforcement, also in the paper-making system which exists so much.

[0002]

[Description of the Prior Art] In recent years, as for the supply situation of the bolt which is the raw material of paper, it has been [steadily worsening] a technical problem with the important increment in the rate of an use rate of used paper. Moreover, closed \*\* in the manufacture process of paper or the paper board is the situation which is not avoided by part of an environmental cure, and paper-making conditions, such as deterioration of water quality and a rise of water temperature, are getting worse increasingly in connection with it. The calcium-carbonate concentration in a paper-making system increases, and calcium ion exists in the paper-making system so much as the amounts of use, such as magazine used paper, increase especially or carbonation of a paper-making system progresses.

[0003] Moreover, in the paper manufacture process of such paper or the paper board, the acrylamide system polymer of anionic, cationicity, or both sexes is conventionally used widely as a paper reinforcing agent. Fixable [to the pulp of a paper reinforcing agent] falls, and it is becoming impossible however, to discover the effectiveness as a paper reinforcing agent enough by closed \*\* of the increment in the rate of a used paper compounding ratio, or wastewater, as a result of a lot of impurity's (calcium ion's etc.) existing in a paper-making system. That is, although the acrylamide system polymer paper reinforcing agent with ionicity is fixed to pulp with electrostatic attraction, if calcium ion exists so much, the desired paper durability enhancing effect is not acquired.

[0004]

[Problem(s) to be Solved by the Invention] As for this invention, also in the paper-making system in which calcium ion exists so much, fixable [to pulp] is good, and it aims at offering the approach of manufacturing the paper or the paper board which has the outstanding paper durability reinforcement.

[0005]

[Means for Solving the Problem] As a result of repeating examination wholeheartedly, when using the acrylamide (meta) system water-dispersion macromolecule which contains a specific phosphoric-acid radical as a paper reinforcing agent that the technical problem of said conventional technique should be solved, this invention persons came to complete a header and this invention for the ability of the paper or the paper board which has the outstanding paper durability reinforcement to be manufactured, even if calcium ion was the paper-making system which exists so much.

[0006] That is, this invention is general formula (1): [0007] as a paper reinforcing agent to the pulp slurry containing 50 ppm - 5000 ppm of calcium ion.

[Formula 5]

[0008] (-- the inside of a formula and X are the same respectively -- or it differs and the hydrocarbon group or alkali-metal atom of a hydrogen atom and carbon numbers 1-4 is expressed.) -- after adding the acrylamide (meta) system water-dispersion macromolecule containing the phosphoric-acid radical expressed, it is related with the manufacture approach of the paper or the paper board characterized by carrying out paper making.

[0009]

[Embodiment of the Invention] The acrylamide (meta) system water-dispersion macromolecule containing the phosphoric-acid radical expressed with said general formula (1) of this invention is a water-dispersion macromolecule obtained by carrying out the polymerization of the acrylamide (meta), and if said phosphoric-acid radical is contained in the water-dispersion macromolecule concerned, especially the approach of introducing said phosphoric-acid radical will not be limited.

[0010] The acrylamide (meta) system water-dispersion macromolecule containing such a phosphoric-acid radical copolymerizes the monomer containing the phosphoric-acid radical expressed with acrylamide (meta) and said general formula (1) as a main constituent, and is obtained.

[0011] Although it sets to this invention, and it can be independent-used or these good (it is the same semantics as (meta) hereafter) can use acrylamide or methacrylamide together with acrylamide (meta), it is good to carry out independent use of the acrylamide from the field of economical efficiency.

[0012] moreover, as an example of the monomer containing the phosphoric-acid radical expressed with said general formula (1) For example, polyethylene-glycol (meta) acrylate phosphate, 2-(diethoxy phosphinyl) (oxy-) ethyl (meta) acrylate, Bis(meta) (bitter taste roil oxy-ethyl) hydro gene phosphate, Monochrome (2-(meta) acryloyloxyethyl) acid phosphate, Diphenyl-2-(meta) AKURO yloxy ethyl phosphate, 2-hydroxyethyl (meta) bitter taste roil phosphonic acid, 2-(meta) acrylamide-isobutane phosphonic acid, these alkali-metal salts, etc. are raised.

[0013] each amount of the monomer used in the case of copolymerizing the phosphoric-acid radical content monomer expressed with the aforementioned (meta) acrylamide and said general formula (1) as a main constituent -- the total mol sum of a monomer -- receiving -- usually -- acrylamide (meta) -- about 90-99.9 mol % -- desirable -- about 92-99.5 mol % -- it is -- on the other hand -- a phosphoric-acid radical content monomer -- about 0.1-10 mol % -- it is 0.5 - eight-mol % preferably.

[0014] moreover, the monomer in which the acrylamide (meta) system water-dispersion macromolecule containing the phosphoric-acid radical of this invention contains the phosphoric-acid radical expressed with the aforementioned (meta) acrylamide and said general formula (1) -- in addition, what copolymerizes the anionic monomer except the monomer containing the phosphoric-acid radical expressed with a cationic monomer and/or said general formula (1) as a main constituent, and is obtained is included. The acrylamide (meta) system water-dispersion macromolecule which copolymerized these ionicity monomer is desirable at the point fixable [ whose / to pulp ] improves.

[0015] The vinyl monomer which contains the quarternary ammonium salt obtained by the reaction of the salts of inorganic acids, such as dimethylaminoethyl (meta) acrylate, diethylaminoethyl (meta) acrylate, dimethylaminopropyl (meta) acrylamide, and diethylamino propyl (meta) acrylamide, or an organic acid or this the 3rd class amino-group content vinyl monomer, and the fourth class-ized agents, such as methyl chloride, benzyl chloride, a dimethyl sulfate, and epichlorohydrin, as a cationic monomer, for example is raised.

[0016] Moreover, as an anionic monomer except the monomer containing the phosphoric-acid radical expressed with said general formula (1), the sodium salt of organic sulfonic-acids [ , such as dicarboxylic acid; vinyl sulfonic acids, such as monocarboxylic acid; maleic acids, such as an acrylic acid (meta) and a crotonic acid a fumaric acid, an itaconic acid, muconic acid, and a citraconic acid a styrene sulfonic acid, a metallyl sulfonic acid, and 2-acrylamido-2-methyl propane sulfonic acid, ]; or these various organic acids, potassium salt, etc. are raised, for example.

[0017] The amount of each monomer used in the case of using the anionic monomer except the monomer containing the phosphoric-acid radical expressed with a cationic monomer and/or said general formula (1) is as follows to the total mol sum of a monomer. namely, -- usually -- acrylamide (meta) -- about 80-99.8 mol % -- it is about 80-99.4 mol % preferably. When not filling to 80-mol%, it is hard to have sufficient paper durability effectiveness. on the other hand -- a phosphoric-acid radical content monomer -- about 0.1-10 mol % -- it is 0.5-8-mol % preferably. moreover, total of the monomer which contains preferably the phosphoric-acid radical expressed with an anionic monomer and a general formula (1) concerned when using the anionic monomer except the monomer which contains about 0.1-10 mol % and the 0.2-8-mol phosphoric-acid radical which is % and is expressed with said general formula (1) when a cationic monomer is used for the amount of the ionicity monomer used -- 0.1 - ten-mol % -- it is 0.2 - eight-mol % preferably.

[0018] Furthermore, in addition to said monomer, the acrylamide (meta) system water-dispersion macromolecule of this invention can copolymerize a cross-linking monomer and other monomers as a constituent as occasion demands in the range which does not have a bad influence on the engine performance.

[0019] As a cross-linking monomer, the vinyl polymer which has chain transfer nature substituents, such as 4 functionality monomers, such as 3 organic-functions monomers, such as 2 organic-functions monomer [ , such as ethylene glycol di(metha)acrylate, a diaryl amine, and N-methylol acrylamide ], triaryl isocyanate, N, and N-diaryl acrylamide, and tetra-allyloxy ethane, and allyl compound (meta) acrylate, diethylene-glycol monochrome (meta) acrylate, dimethyl acrylamide, is raised, for example. the case where a cross-linking monomer is used -- the amount used -- the total mol sum of a monomer -- receiving -- usually -- or less about 5 mol % -- it is less than [ 2 mol % ] preferably. The copolymer obtained becomes gel and is not desirable when exceeding five-mol %.

[0020] As other monomers, the ester of anionic monomers, such as N permutation (meta) acrylamides, such as t-octyl acrylamide, an acrylic acid (meta), and a maleic acid, and alcohol, styrene, alpha methyl styrene, vinyltoluene, acrylonitrile, the methyl vinyl ether, isopropyl acrylamide, vinyl acetate, an alpha olefin, etc. are raised, for example. the case where other monomers are used -- the amount used -- the total mol sum of a monomer -- receiving -- or less about 10 mol % -- it is less than [ 8 mol % ] preferably. In exceeding ten-mol % (meta), the rate of acrylamide decreases, and the paper which has sufficient paper durability effectiveness is hard to be obtained.

[0021] Various well-known approaches can be conventionally used for the method of copolymerizing said monomer and obtaining the acrylamide (meta) system water-dispersion macromolecule of this invention. For example, said each monomer and water can be taught to a predetermined reaction container, the usual radical polymerization initiators, such as a redox system polymerization initiator of the form which combined persulfate, such as potassium persulfate and ammonium persulfate, or these and the reducing agent like a sodium hydrogensulfite, can be added, and the acrylamide (meta) system water-dispersion macromolecule of this invention can be obtained by warming under churning.

[0022] The weight average molecular weight of the obtained acrylamide (meta) system water-dispersion macromolecule is usually 100,000 to about 10 million, and viscosity is converted into 10 % of the weight of solid content concentration, and is usually the description below 20000cps (25 degrees C) extent preferably below 30000cps (25 degrees C) extent.

[0023] The manufacture approach of the paper of this invention or the paper board calcium ion to the pulp slurry included 50 ppm - 5000 ppm It is what is characterized by carrying out paper making after adding the aforementioned (meta) acrylamide system water-dispersion macromolecule as a paper reinforcing agent. The pulp slurry contains a lot of calcium ion, and the same conditions as the manufacture approach of of the common paper or the common paper board can be adopted except using the acrylamide (meta) system water-dispersion macromolecule of said specific ionicity as a paper reinforcing agent.

[0024] Namely, what is necessary is just to usually add a paper reinforcing agent to pulp solid content at about (solid content) 0.1 - 1% of the weight of an operating rate. Moreover, the addition stage of a paper reinforcing agent can be set up suitably, and ranging from the acidic range to alkalinity, pH of a paper-

making system reaches far and wide, and can be applied. Moreover, if it determines suitably according to paper-making conditions, it is sufficient for the class of pulp, and the class of paper-making Hokusui, and they can carry out combination addition of a sizing compound, a fixing agent, the loading material, etc. suitably.

[0025] In addition, the calcium ion concentration in a pulp slurry is the value measured with the pocket water quality meter made from LASA (Cuvette Test LCK327).

[0026]

[Effect of the Invention] the paper-making system in which calcium ion exists so much according to this invention -- also setting -- a ratio -- the paper or the paper board which has paper durability reinforcement, such as bursting strength, breaking length, and surface reinforcement, can be offered.

[0027]

[Example] Hereafter, an example and the example of a comparison are given and this invention is explained more concretely. In addition, each of sections and %s is based on weight criteria.

[0028] The ion-exchange-water 500 section was taught to the flask equipped with example of manufacture 1 agitator, a dropping funnel (A), a dropping funnel (B), a thermometer, a reflux cooling pipe, and nitrogen gas installation tubing. On the other hand, the ammonium persulfate 0.21 section and the ion-exchange-water 100 section were taught to the dropping funnel (A) for the acrylamide 170 section, the ion-exchange-water 230 section, and the monochrome (2-methacryloiloxy-ethyl) acid phosphate 14 section as a polymerization initiator at the dropping funnel (B). After removing the oxygen in all the systems of reaction through nitrogen gas, the inside of the system of reaction was heated to 80 degrees C under churning, and it was dropped at it from the dropping funnel (A) and the dropping funnel (B) from the time of becoming 80 degrees C, having applied it to coincidence for 2 hours. Subsequently, ion exchange water was added and the water dispersion of 10.4% of solid content and an acrylamide system macromolecule with a viscosity of 7300cps was obtained.

[0029] In the example 1 of example of manufacture 2 manufacture, except having changed into the acrylamide 159 section, the ion-exchange-water 230 section, the dimethylaminopropyl acrylamide 15.6 section, the 80% acrylic-acid 4.5 section, and the monochrome (2-methacryloiloxy-ethyl) acid phosphate 14 section what was taught to the dropping funnel (A), the same actuation as the example 1 of manufacture was performed, and the water dispersion of 10.4% of solid content and an acrylamide system macromolecule with a viscosity of 8500cps was obtained.

[0030] In the example 3 of manufacture - the example 1 of 8 manufactures, as shown in Table 1, even if few [ either ] among the class of monomer component, or its amount used (presentation ratio: mol %), a kind was changed, and also the same actuation as the example 1 of manufacture was performed, and the water dispersion of an acrylamide system macromolecule was obtained. the description of each obtained water dispersion -- a value is shown table 2.

## CLAIMS

[Claim(s)]

[Claim 1] the pulp slurry containing 50 ppm - 5000 ppm of calcium ion -- as a paper reinforcing agent -- general formula (1): -- [Formula 1]

(-- the inside of a formula and X are the same respectively -- or it differs and the hydrocarbon group or alkali-metal atom of a hydrogen atom and carbon numbers 1-4 is expressed.) -- the manufacture approach of of the paper or the paper board characterized by carrying out paper making after adding the acrylamide (meta) system water-dispersion macromolecule containing the phosphoric-acid radical expressed.

[Claim 2] the acrylamide (meta) system water-dispersion macromolecule containing a phosphoric-acid radical -- acrylamide (meta) and general formula (1): -- [Formula 2]

(-- the inside of a formula and X are the same respectively -- or it differs and a hydrogen atom, a carbon number 1 - 6 hydrocarbon group, or an alkali-metal atom is expressed.) -- the manufacture approach of of the paper according to claim 1 or the paper board which is the water-dispersion macromolecule which becomes considering the monomer containing the phosphoric-acid radical expressed as a main constituent.

[Claim 3] The manufacture approach of of the paper according to claim 2 or the paper board which is the water-dispersion giant molecule with which the acrylamide (meta) system water-dispersion giant molecule containing a phosphoric-acid radical becomes considering a cationic monomer as a constituent further.

[Claim 4] the acrylamide (meta) system water-dispersion macromolecule containing a phosphoric-acid radical -- further -- general formula (1): -- [Formula 3]

(-- the inside of a formula and X are the same respectively -- or it differs and a hydrogen atom, a carbon number 1 - 6 hydrocarbon group, or an alkali-metal atom is expressed.) -- the manufacture approach of of the paper according to claim 2 or 3 or the paper board which is the water-dispersion macromolecule which becomes considering the anionic monomer except the monomer containing the phosphoric-acid radical expressed as a constituent.

[Claim 5] General formula (1): [Formula 4]

(-- the inside of a formula and X are the same respectively -- or it differs and a hydrogen atom, a carbon number 1 - hydrocarbon group, or an alkali-metal atom is expressed.) -- the monomer containing the phosphoric-acid radical expressed -- 0.1-10-mol% of the constituent of an acrylamide (meta) system water-dispersion macromolecule -- the manufacture approach of of the paper according to claim 2, 3, or 4 or the paper board which it comes to contain.
